KUBERNETES, EXPLAINED 01

# What a Pod actually is.

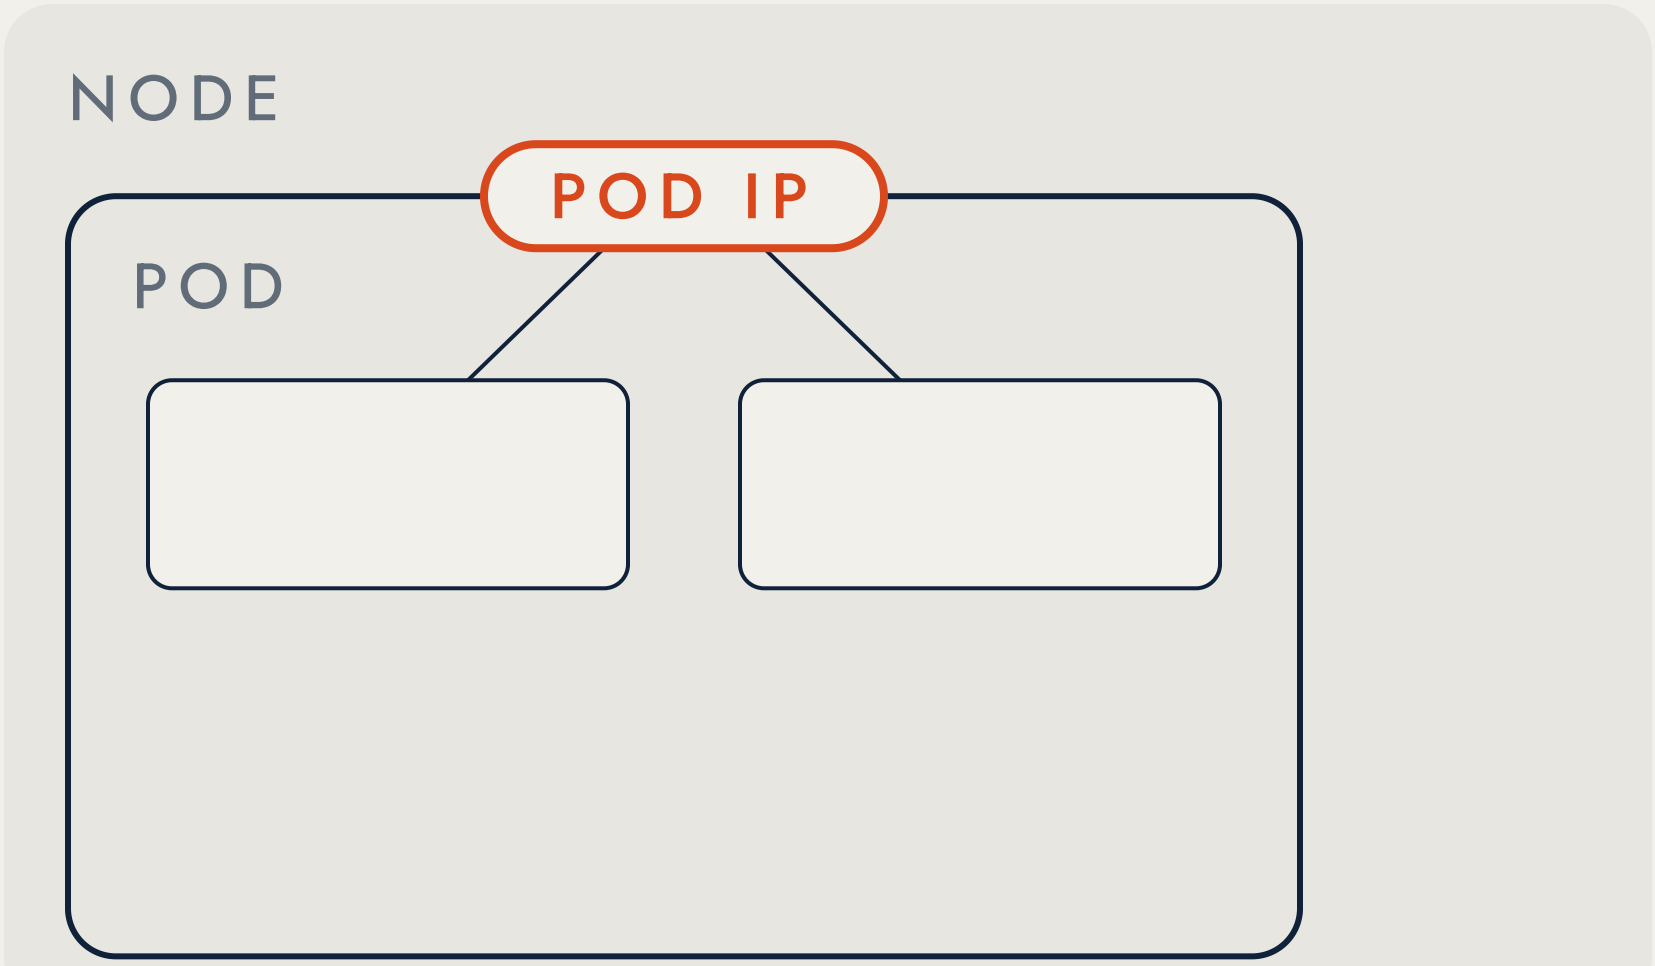

# The smallest unit you deploy.

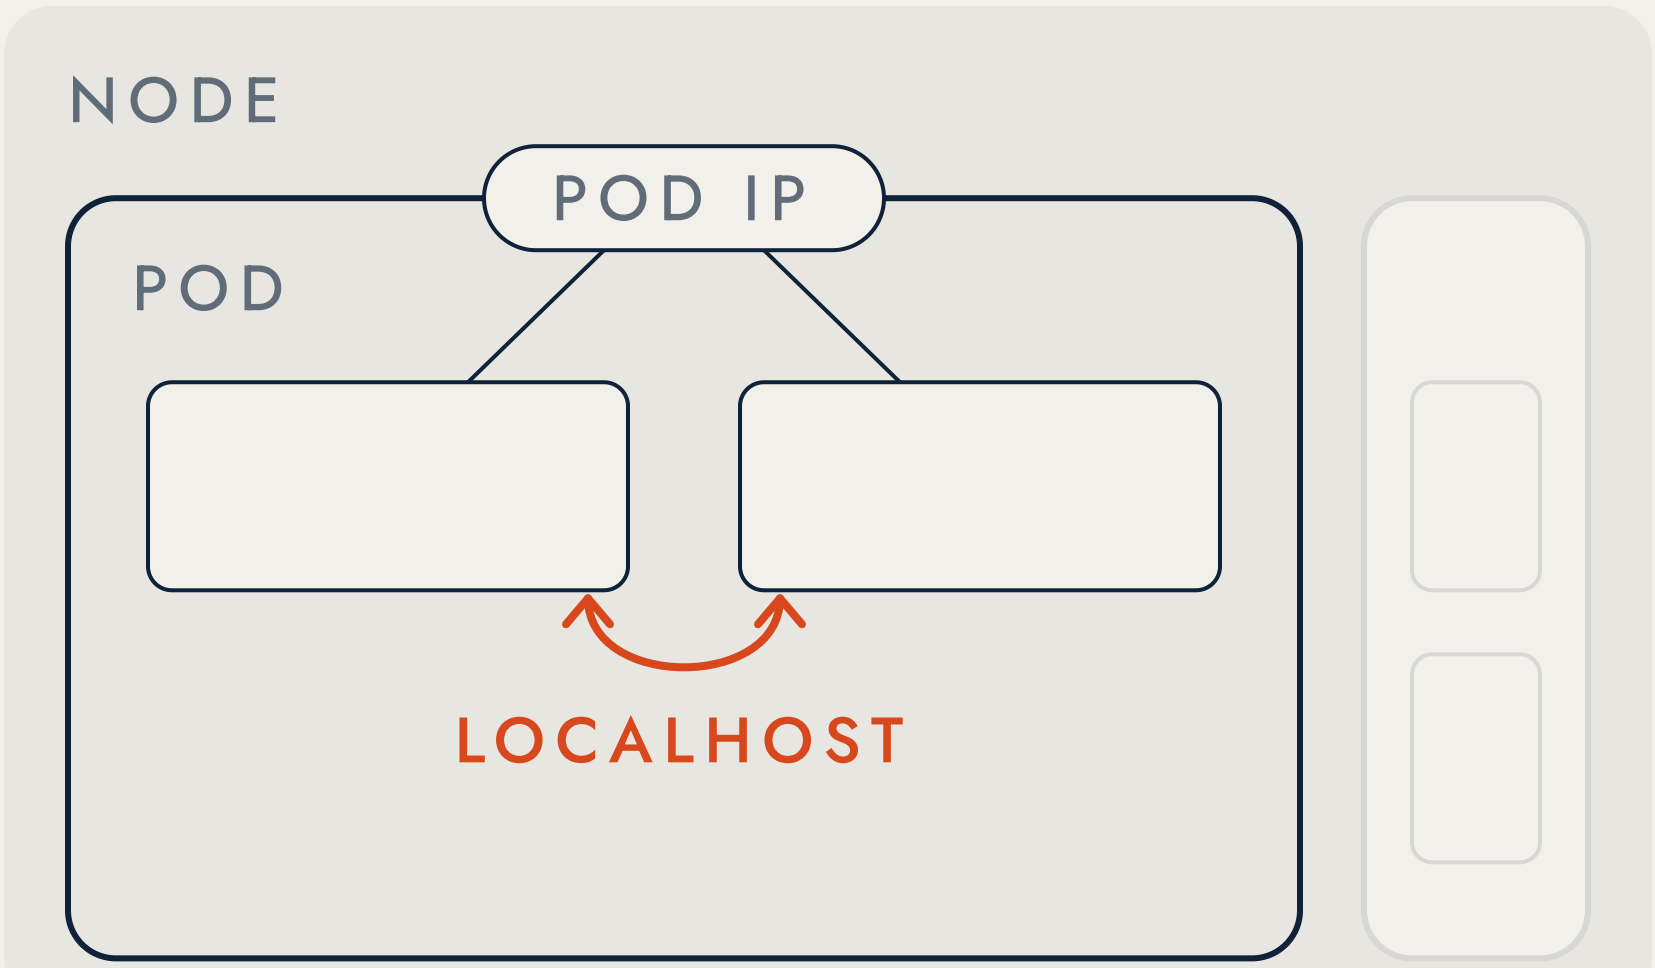

A Pod is a group of one or more containers, on the same machine.

# Containers share the Pod's IP.

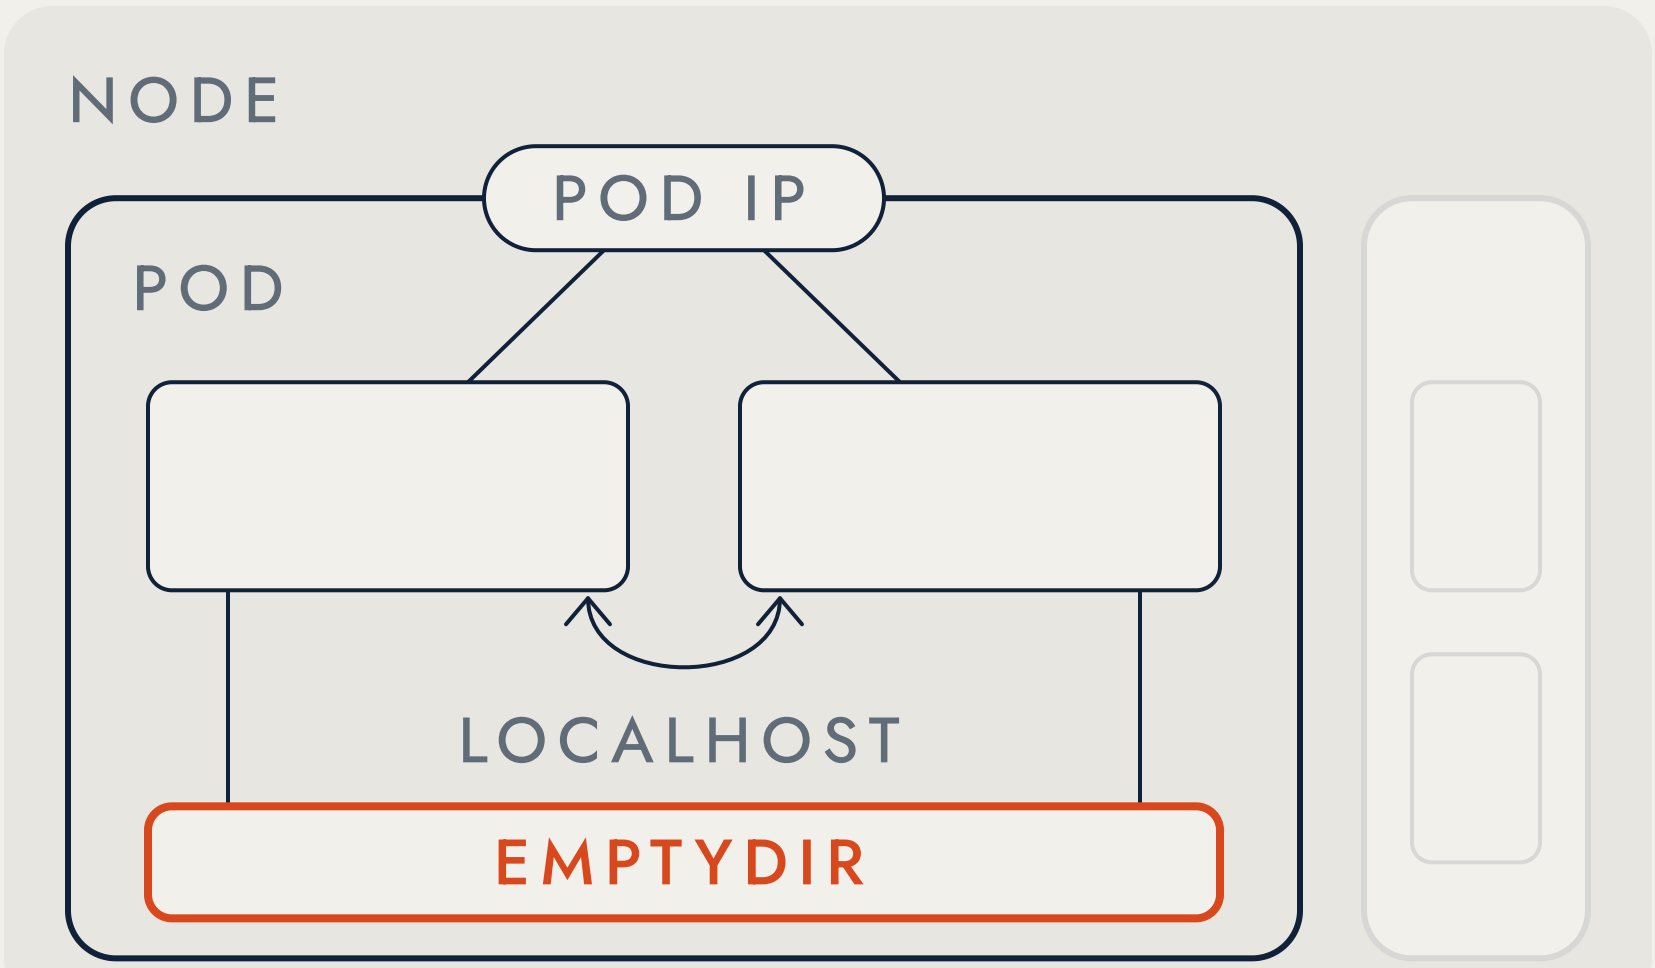

Every container in your Pod shares its network namespace: the IP address and the ports.

# Neighbours talk over localhost.

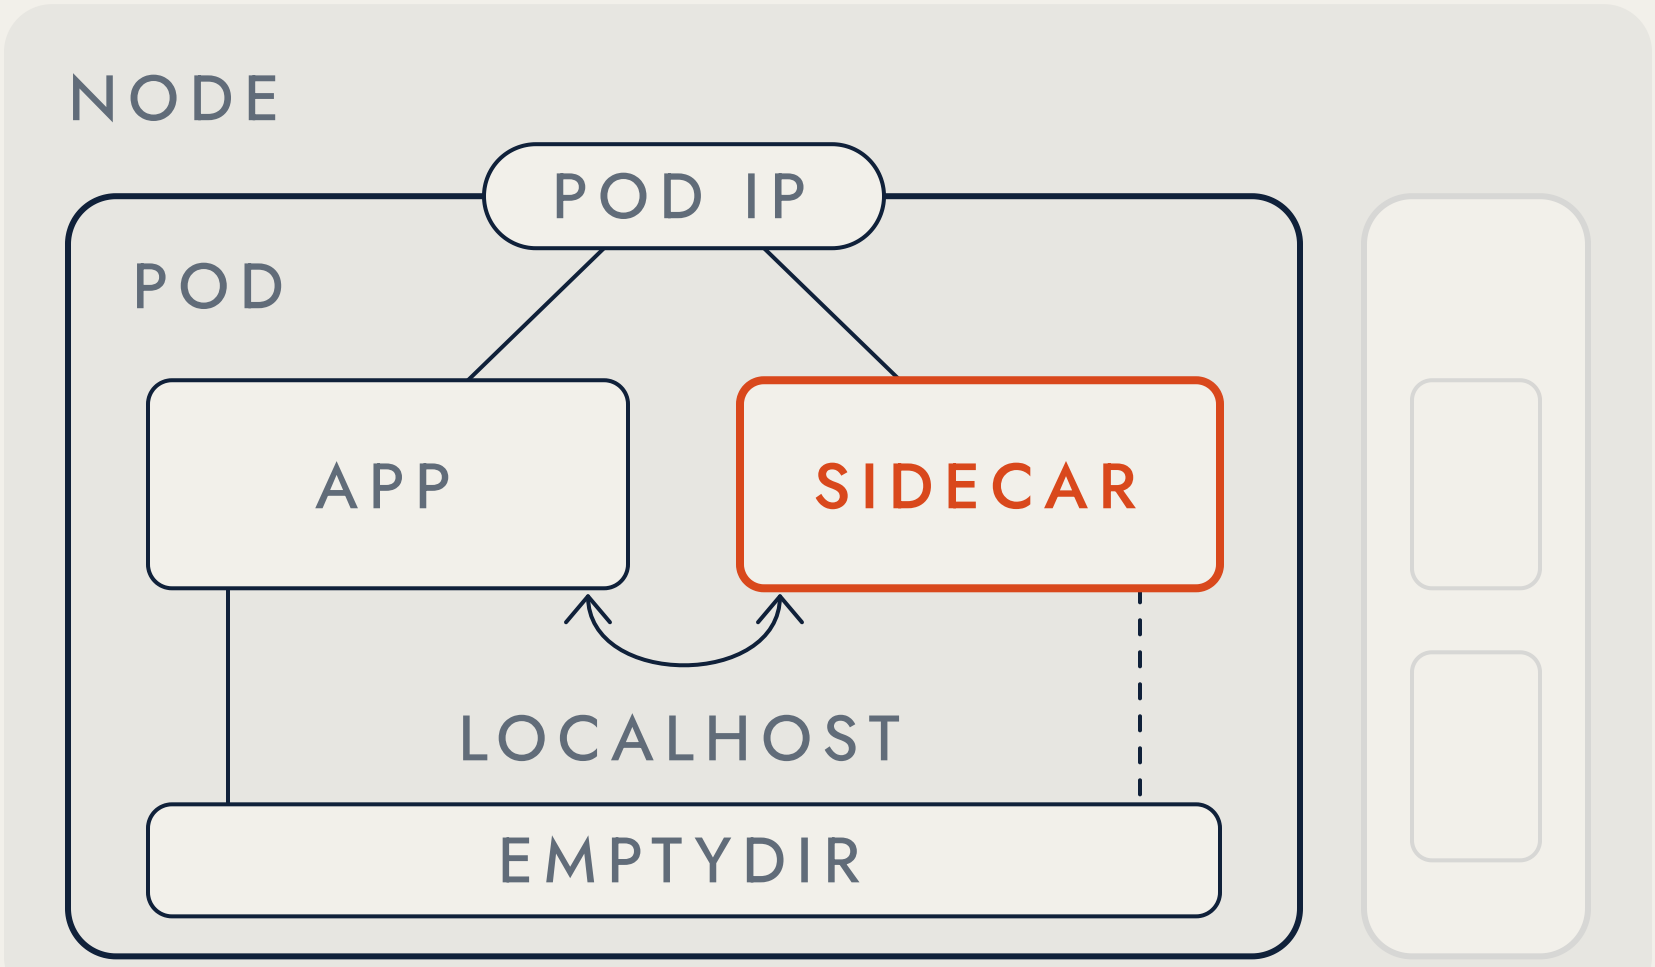

Inside a Pod, and only there, your containers reach each other on localhost.

# Shared files, one volume.

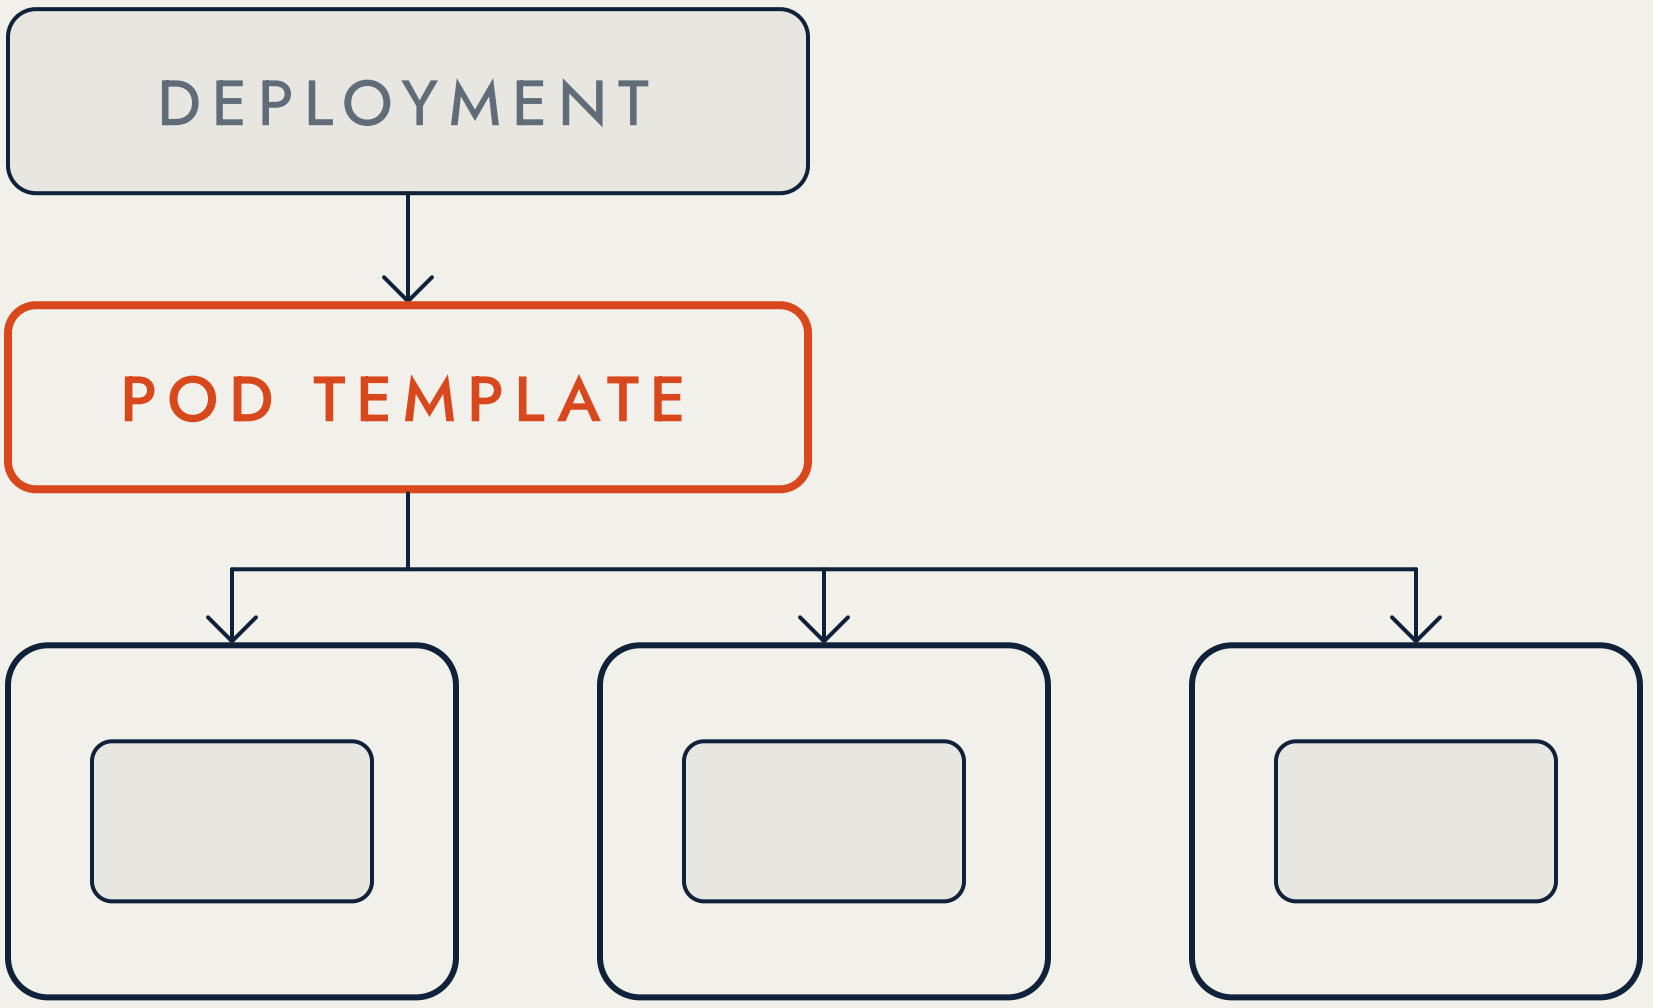

Every container in your Pod can read and write the same files in an emptyDir volume.

# A sidecar runs beside the app.

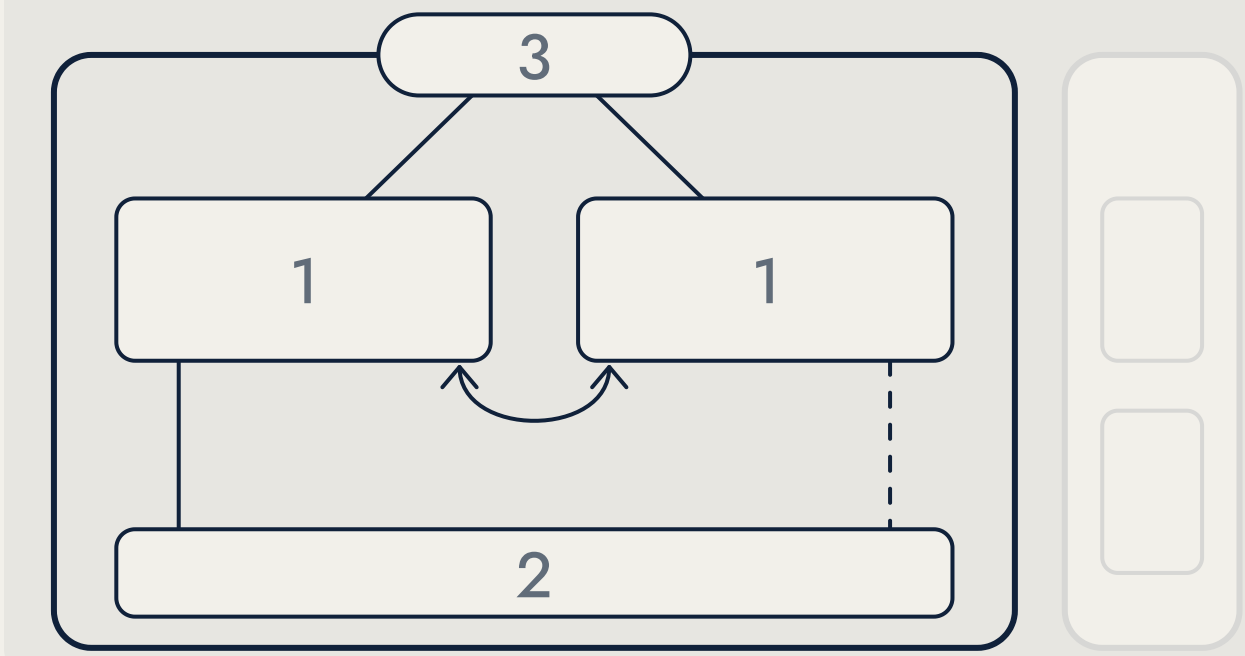

Another container in your Pod. It shares the app's network and, if you choose, its volumes.

# Pods come from a template.

You'll rarely create a Pod by hand. A Deployment's controller makes Pods from a Pod template.

# Here's the short version.

"A Pod is a group of one or more containers[1], with shared storage[2] and network[3] resources, and a specification for how to run those containers."
